Abstract

This study examined the relative influence of genetic versus environmental factors on specific aspects of eating behavior. Adult monozygotic twins (22 pairs and 3 singleton reared apart, 38 pairs and 9 singleton reared together, age 18–76 years, BMI 17–43 kg/m²) completed the Three Factor Eating Questionnaire. Genetic and environmental variance components were determined for the three eating behavior constructs and their subscales using model-fitting univariate and multivariate analyses. Unique environmental factors had a substantial influence on all eating behavior variables (explaining 45–71% of variance), and most strongly influenced external locus for hunger and strategic dieting behavior of restraint (explaining 71% and 69% of variance, respectively). Genetic factors had a statistically significant influence on only 4 variables: restraint, emotional susceptibility to disinhibition, situational susceptibility to disinhibition, and internal locus for hunger (heritabilities were 52%, 55%, 38% and 50%, respectively). Common environmental factors did not statistically significantly influence any variable assessed in this study. In addition, multivariate analyses showed that disinhibition and hunger share a common

None of the authors had a personal or financial conflict of interest.

The authors' responsibilities were as follows – SJE: analyzed the data and wrote the manuscript, which was reviewed and modified by all authors; MCN: provided guidance regarding the experimental design and statistical analyses; PJF: coordinated the study; AHL: provided guidance regarding data analysis and manuscript goals; ASG and ES: participated in data collection and medical supervision of the study; MAM: performed preliminary data cleaning and analyses; TJB: provided assistance in subject recruitment and guidance in study design; SBR: designed and directed all aspects of the study and contributed to the manuscript.

influence, while restraint appears to be a distinct construct. These findings suggest that the majority of variation in eating behavior variables is associated with unique environmental factors, and highlights the importance of the environment in facilitating specific eating behaviors that may promote excess weight gain.

Keywords

Disinhibition; restraint; hunger; obesity; heritability; environment

INTRODUCTION

Eating behavior is known to play an important role in energy regulation [1], and the eating behavior construct, disinhibition is correlated with current body mass index (BMI), prior weight gain over 20 years, and weight regain following weight loss [2–8]. However, the extent to which different eating behaviors are influenced by genes versus environmental factors remains uncertain.

Aspects of eating behavior such as dietary restraint and food preferences are known to be transmissible between family generations [9–11], but currently there are only six reports on the heritability of different eating behaviors [12–17] assessed using a full or shortened version of the validated Three Factor Eating Questionnaire [18]. Moreover, estimates for the heritability of the three most widely recognized eating behavior constructs – disinhibition, restraint and hunger – vary widely even when the full Eating Inventory was used for determination. In addition, to our knowledge, the heritabilities of the more recently proposed subscales of eating behavior have not been estimated. These subscales were proposed to identify specific aspects of eating behavior, and although low heritability estimates do not necessarily indicate high malleability of a trait, subconstructs with low heritability and/or high environmental transmission estimates may potentially have greater utility in informing effective targets for behavior change. Previous reviews have recognized the general lack of data in this area and have emphasized the need for much more research [19].

The objectives of this study were to quantify the genetic, common environmental and unique environmental influences on eating behavior constructs and subscales assessed by the Three Factor Eating Questionnaire, and to determine the extent to which genetic and environmental influences are shared by restraint, disinhibition, and hunger. As described elsewhere [20] data was collected as part of the Tufts Twin Study. MZA twin pairs constitute a particularly valuable group for assessing trait heritability because although they are extremely rare they provide substantial statistical power to estimate heritability compared to studies using other types of populations [21].

MATERIALS AND METHODOLGY

Subjects

As described elsewhere [20], subjects were 132 healthy adult male or female monozygotic twins aged 18–76 years who participated in the Tufts Twin Study. They included 60 monozygotic twin pairs who were either reared apart since near birth (22 pairs) or together

(38 pairs), and 12 singleton monozygotic twins (3 MZA, 9 MZT) whose twin did not participate in the study. Eligibility criteria included being healthy at the time of study and willing to travel to Boston to participate in the study. Subjects were given a stipend for their participation in the study. The protocol was approved by the Institutional Review Board at Tufts University and all subjects gave written and informed consent.

Protocol

Each subject was admitted to the Metabolic Research Unit at the HNRCA for approximately four days of observation and completed a variety of examinations and questionnaires concerning energy regulation. During the 4-day inpatient study at Tufts, subjects slept and ate all meals in the research center from a self-selection menu of typical foods [20]. BMI was calculated from measured weight and height.

Eating Behavior Measures

Subjects completed the Three Factor Eating Questionnaire [18], which consists of 51 questions contributing towards the scoring of constructs and subscales. The questionnaire was completed with minimal environmental distractions and not in the presence of other people, including their twin.

As originally developed by Stunkard and Messick, the Three Factor Eating Questionnaire characterizes three main constructs of eating behavior - disinhibition, restraint and hunger [18]. Since the development of the questionnaire, ten subscales have been proposed [22, 23]. Descriptions of these constructs and subscales are presented in Appendix A.

Questionnaires from the 132 subjects were used to calculate the three original constructs and the ten subscales with scoring as described in the original reports. Of these questionnaires, 34 had some missing answers; in this case we used our previously developed method for scaling constructs and subscales [5]. When <15% of the scale's questions were unanswered, proportional scales were calculated as $[(\text{raw score}/(\text{total number of possible answers} - \text{number of missing answers})) \times \text{total number of possible answers}]$. When >15% of the scale's questions were unanswered, a score could not be calculated and data for the particular construct or subscale was considered missing. Appendix B summarizes our scoring calculations.

Statistical Analysis

As described elsewhere [20], descriptive statistics were calculated using SAS 9.1 [24]. Genetic and environmental influences on eating behavior were assessed using intrapair (intra-class) correlations and model-fitting analyses.

Intrapair (intra-class) MZA and MZT correlation coefficients were calculated for all constructs and subscales as a measure of within-pair similarity using SPSS 15.0 [25]. MZA intrapair correlations are a simple estimate of heritability, because their covariance consists solely of the genetic component of variance [26]. However, this technique of heritability estimation is inferior to model-fitting analyses because it may lead to nonsensical estimates of heritability, it does not easily generalize to the multivariate genetic factor models, it is

inefficient when there are missing data, and it does not optimally combine data from multiple groups [27].

Model-fitting analyses are based on the decomposition of variance into genetic (G), common or shared environmental (C), and unique or non-shared environmental (E) components. Genetic variance (V_G) is caused by differences in genes between individuals. The distinction between genetic variance due to dominance versus additive effects cannot be evaluated in an MZT/MZA study because both types share 100% of their genetic material, and therefore all additive and non-additive genetic variance components. Common environmental variance (V_C) is due to environmental factors responsible for resemblance between family members, while unique environmental variance (V_E) is due to environmental factors that contribute to differences between family members [26]. Unique environmental variance comprises any variance that is not due to genetic or common environmental factors, including variance due to measurement error. Total phenotypic variance (V_P) can be represented as $V_P = V_G + V_C + V_E$. Broad heritability is defined as the proportion of total phenotypic variance in a given trait that is attributable to genotypic variance, including all additive and nonadditive effects of genetic factors [26]. This quantity is distinct from the narrow sense heritability, which refers to only the additive genetic variance.

Variance decomposition was applied in the MZA/MZT design, where it is assumed that all monozygotic twin pairs share 100% of their genetic material. MZT pairs share all common environmental factors (such as parents, siblings, home, and economic factors), and MZAs do not correlate for these common environmental effects. That is, it is assumed that MZAs are placed in homes selected at random from the population. These relationships can be depicted in a path diagram (Fig. 1). The covariance of MZAs (COV_{MZA}) is V_G and the covariance of MZTs (COV_{MZT}) is $V_G + V_C$ [20].

As described elsewhere, the MZA/MZT twin model used here is based on the following assumptions: (1) traits follow polygenic inheritance; (2) the observed phenotypic variance is a linear additive function of genetic and environmental variances; (3) genetic and environmental effects are uncorrelated and there is no genotype by environmental interaction; (4) there is no selective placement (non-random adoption of twins into similar families); (5) genetic and environmental effects are of the same magnitude in males and females [20,28]. Note also that any genetic effects of assortative mating contribute to V_G and that differences in methylation within a twin pair contribute to V_E .

Model-fitting analyses were performed using Mx, a structural equation modeling software package [28]. Mx fits the MZA/MZT GCE model to the raw observed data. It estimates parameters using maximum likelihood, and computes goodness-of-fit statistics based on minus twice the natural logarithm of the likelihood ($-2\ln L$). Likelihood ratio tests (LRT) are used to test hypotheses, because under certain regularity conditions, the difference in $-2\ln L$ between nested models (which differ because one or more parameters are constrained to equal each other or specific values) is asymptotically distributed as χ^2 with degrees of freedom (df) equal to the difference in the number of free parameters in the two models. However, under the null hypothesis that a variance component is zero, the likelihood-ratio test is distributed as a 50:50 mixture of χ^2 with 1 degree of freedom, and zero.

Univariate analyses were performed to quantify and compare the genetic, common environmental and unique environmental influences on eating behavior constructs assessed by the Eating Inventory, including subscales of restraint, disinhibition, and hunger. All the subscales were treated as ordinal variables because they had less than ten distinct categories. Restraint, disinhibition and hunger – which had greater than ten categories – were analyzed both as ordinal and continuous variables, to compare results. Age and gender were included as covariates.

Multivariate analysis was used to determine the extent to which genetic and environmental influences are shared by restraint, disinhibition, and hunger. Age and gender were again included in the analyses as covariates. Two multivariate models – a Cholesky decomposition and a common pathway multivariate model – were compared on the basis of likelihood and parsimony to determine the model with the best fit to the data. The difference in likelihood was assessed by calculating the difference in $-2\ln L$ between models. Parsimony was assessed by Akaike's Information Criterion (AIC), which may be computed as $-2\ln L - 2df$, where the more negative value indicated the most parsimonious model.

A Cholesky decomposition model is used to estimate the genetic and environmental covariances across the three variables: restraint, disinhibition, and hunger [29]. In this approach, the observed variables are influenced by three latent G factors, three latent C factors, and three latent E factors. The model is specified such that the first genetic factor influences all three variables, the second genetic factor influences the final two variables, and the third genetic factor influences only the last variable. The same pattern is specified for the common and unique environmental factors. This model is 'saturated' in that it estimates all genetic and environmental variances and covariances subject to the constraint that the matrices of these variance components are non-negative definite.

In the common pathway model, a common latent factor influences all of the observed variables; this common factor is in turn influenced by G, C and E latent factors. In addition, there are three specific latent G factors (G_S), three specific latent C factors (C_S), and three specific latent E factors (E_S). These specific factors each affect only one observed variable.

RESULTS

Table 1 shows descriptive statistics of the study population. As described elsewhere [20], the majority of the subjects were female (72% of MZAs and 76% of MZTs) and Caucasian (97% of MZAs and 94% of MZTs). The mean age of the MZA twins (49.1 ± 12.0 years, range of 22–76 years) was significantly different from that of the MZT twins (28.7 ± 7.3 years, range of 18–47 years, $p < 0.0001$). MZTs and MZAs differed significantly in weight and body mass index ($p < 0.01$), but not when the data were adjusted for age ($p > 0.05$). Of all the eating behavior constructs, the two groups differed significantly only in restraint and two of the restraint subscales (flexible and rigid restraint), with MZTs scoring higher than MZAs ($p < 0.05$). The number of subjects contributing to mean scores varies slightly between constructs and subscales because individual questions were occasionally left unanswered.

Table 2 shows the intrapair (intra-class) correlations for MZAs and MZTs. MZT correlations were greater than MZA correlations for restraint, disinhibition, attitude to self-regulation, habitual susceptibility, and flexible restraint, suggesting that common environmental factors play a role in these eating behaviors. MZA correlations are a simple estimate of heritability, showing significant estimates ranging from 0.47 (situational susceptibility) to 0.62 (avoidance of fattening foods) for the various eating behavior constructs. However, as mentioned earlier, this technique of heritability estimation is inferior to model-fitting analyses [27].

Results from the univariate analyses are shown in Fig. (2) with confidence intervals for variance component estimates reported in Table 3. Results for restraint, disinhibition and hunger were similar when the constructs were analyzed as ordinal versus continuous variables, so only the results from the continuous variable analyses are presented. Only restraint, emotional and situational susceptibility to disinhibition, and internal locus for hunger had statistically significant heritability estimates, those being 52%, 55%, 38% and 50%, respectively. The proportion of variance due to common environmental factors was not statistically significant for any of the constructs or subscales, while the proportion of variance of constructs and subscales due to unique environmental factors (which is performed statistically significant because the likelihood of the data approaches zero in the limit as the estimate of E does) ranged from 45% to 71%.

Multivariate model-fitting analyses were also conducted on restraint, disinhibition and hunger (treated as continuous variables) to determine the extent to which they share genetic and environmental influences. Variances-covariance and correlation matrices for restraint, disinhibition, and hunger are shown in Table 4. The difference in fit ($-2\ln L$) between the Cholesky decomposition and the common pathway model was 6.7 with 4 degrees of freedom. Since the p-value associated with this chi-square distribution is 0.152, the two models do not significantly differ in fit, and therefore the simpler common pathway model is judged acceptable. Fig. (3) shows a path diagram for the common pathway model, with standardized parameter estimates and confidence intervals drawn along the paths and statistically significant paths represented as darkened lines. Disinhibition and hunger appeared to share a common influence, which was influenced (although not statistically significantly) by genetic and environmental factors. Specific genetic and unique environmental factors statistically significantly influenced restraint; specific environmental factors did not statistically significantly influence disinhibition; and a unique environmental factor statistically significantly influenced hunger. The proportion of variance due to genetic and environmental factors for each observed measure is shown in the corresponding square in Fig. (3). Genetic variance in restraint was statistically significant with heritability estimated at 51%. The variance of disinhibition and hunger was explained mostly by environmental factors, with non-statistically significant heritabilities of 34% and 36%, respectively. These values differed slightly from the univariate estimates because multivariate analyses exploit additional data in the form of covariances between variables, both within-person and across-twins.

DISCUSSION AND CONCLUSION

This study of adult MZA and MZT pairs provides, to our knowledge, the first report of the genetic, common environmental and unique environmental influences on eating behavior subscales, and adds to the currently small existing literature on the heritability of the original three eating behavior constructs in a unique population recognized to have relatively little bias in estimates of heritability. The primary findings of this study were that, out of 14 constructs and subscales, only 4 were significantly heritable, and that unique environmental transmission was particularly high for the external locus for hunger and strategic dieting behavior of restraint. These findings suggest an important role for the environment in influencing eating behaviors that contribute to or maintain excess body fatness.

The four eating behavior constructs and subconstructs that were significantly heritable in this study were restraint, emotional susceptibility to disinhibition, situational susceptibility to disinhibition, and internal locus for hunger (heritabilities were 52%, 55%, 38% and 50%, respectively), traits that have been associated with body fatness and/or weight gain [3, 5, 8, 29, 30]. Concerning restraint, while previous investigations have indicated that dietary restraint in children is strongly influenced by parental behaviors [9, 10], heritability estimates in adults have ranged from 0% to 61% [12–17] and our estimate of 52% is thus near the top end of the reported range. In part, the variability in previous studies may have been due to the different instruments and populations used. For example, classical twin studies using MZ and DZ twins may potentially overestimate heritability because they rely on the "equal environment assumption" which may be violated, though it seems unlikely that such violations do not originate with the phenotype or genotype of the twins. Family studies may alternatively underestimate heritability for a variety of reasons including false paternity [21] and genotype by age interaction, and in the absence of relationships of differing degree require the assumption that shared environment effects are absent. Consistent with the suggestion of less bias in an MZA/MZT population, our results gave generally higher heritability estimates compared to the family studies [12, 15], and lower or non-significant estimates than the MZ/DZ studies [13, 14]. However, it should also be noted that our study population was not particularly large and the age range of the twins was wide, therefore some of the trends observed that did not reach statistical significance could have been due to lack of statistical power.

The ability to partition total variance into genetic, common environmental and unique environmental components by the use of structural equation modelling also showed that all eating behaviors studied were substantially influenced by the unique environment, a finding that is consistent with the increasing prevalence of obesity nationally and worldwide in parallel with changing environmental factors. In contrast to suggestions from two previous classical (MZ vs DZ) twin studies [13, 14], none of the eating behaviors measured in this study was significantly influenced by the common environment. In contrast, unique environmental factors appeared to have a dominant influence on most eating behavior constructs and subscales, and were particularly strong for habitual susceptibility to disinhibition, the external locus for hunger and the restraint subscales, all of which may potentially play an important role in excess weight gain in adulthood and the development of obesity. It is possible that we under-estimated the influence of common environmental

factors if our assumption of zero MZA common environmental co-variance was not true due to selective placement of MZA twin pairs into adoptive families that were similar to one another. However, selective placement is not thought to contribute significantly to MZA common environmental covariance [31]. Furthermore, in addition to the fact that a dominant role for unique environmental influences being entirely consistent with the changing national prevalence of obesity, it is also important to note that unique environment factors as assessed in these analyses include wide variety of influences including the current food environment of the individual which may have an important effect as well as factors specific to individuals during child-rearing years (for example, differing school meal environments), environmental influences after leaving home, and measurement error.

In a multivariate analysis, we also found that disinhibition and hunger are related to each other but unrelated to restraint - a finding that is consistent with a previous report [13]. A relationship between disinhibition and hunger is also consistent with previous work from our group, which showed both an interaction between habitual disinhibition and external hunger in eating behavior models predicting adult weight gain [8], and an association between food cravings (which are associated with disinhibition) and hunger [32]. The underlying reasons for disinhibition and hunger may be linked metabolically are not known, but we speculate that one candidate mechanism may be the cephalic phase of digestion [33, 34], which occurs when the sympathetic nervous system is stimulated by sensory input on available food or thoughts about food and causes physiologic changes including: increased saliva production, increased gastric acid secretions and mobility, and an insulin surge and drop in blood glucose that can increase hunger [35]. As demonstrated by Pavlov's original experiments on associative conditioning in dogs [33], cephalic phase responses to food can be triggered by external factors if food consumption and the external factors occur together over repeated feeding bouts. Based on this premise, a habitual environment favorable for unrestricted eating could lead to high values for both habitual disinhibition and external hunger mediated by cephalic phase anticipatory responses to eating. Further research on the role of the environment in conditioning hunger and disinhibition is needed.

In summary, our results from a unique MZA/MZT population suggest a relatively modest influence of genes and a strong influence of unique environmental factors on eating behaviors. Although studies of this kind do not directly address whether the heritability of eating behaviors reflects the extent to which they can be changed with behavioral weight control or other therapies, our results suggest that environmental factors generally play a substantial role in individual differences in eating behaviors.

APPENDICES

Appendix A: Description of Eating Inventory Constructs and Subscales

Eating Inventory Constructs [3]	
Restraint	Conscious restriction of energy intake to prevent weight gain or promote weight loss by, for example, counting calories and purchasing low calorie food items
Disinhibition	Tendency to overeat in response to different stimuli and triggers
Hunger	Susceptibility to eat in response to perceived physiological symptoms that signal the need for food
Eating Inventory Subscales of Bond <i>et al.</i> [25]	
Restraint	
Strategic Dieting Behavior	Behaviors that might be used to control weight (e.g. deliberately taking small helpings)
Attitude to Self-Regulation	Overarching perspective on eating and weight control (e.g. feeling that life is too short to worry about dieting)
Avoidance of Fattening Foods	Dieting behavior which limits calorie-dense foods
Disinhibition	
Habitual Susceptibility	Recurrent disinhibition triggered by routine circumstances
Emotional Susceptibility	Disinhibition associated with negative affective states
Situational Susceptibility	Disinhibition initiated by specific environmental cues (e.g. social occasions)
Hunger	
Internal Locus for Hunger	Hunger that is interpreted and regulated internally
External Locus for Hunger	Hunger that is triggered by external cues
Restraint Subscales of Westenhoefer [26]	
Flexible Restraint	An adaptable approach to dieting, where forbidden foods can be eaten in limited quantities without guilt
Rigid Restraint	A dichotomized "all-or-nothing" approach to eating and dieting, where individuals diet frequently and avoid forbidden foods, but exhibit behaviors that do not support their dieting goals (e.g. not reducing meal size, not compensating for deviations from the diet)

Appendix B: Eating Inventory and Scoring Summary

Eating Inventory Scoring Summary

The Eating Inventory consisted of 51 questions that contributed to the scoring of eating behavior constructs and subscales. Each question contributed to the score of one of the three original Eating Inventory constructs (restraint, disinhibition, and hunger), and most questions contributed to the score of one or more Eating Inventory subscales, as shown in the following table and questionnaire. Questions were each worth one point; questionnaire answers in bold type accrued one point and answers in regular type accrued zero points. Higher scores indicate greater levels of the eating behavior. If answers were missing, proportional scales were calculated when less than 15% of the scale's questions were unanswered (7). The proportional scale was calculated as:

raw score

$$\frac{\text{total number of possible answers} - \text{number of missing answers}}{\text{total number of possible answers}}$$

When greater than 15% of the scale's questions were unanswered, a score could not be calculated and was considered missing data.

Questionnaire	Scoring	
Construct or Subscale	Range	Questions
Eating Inventory Constructs (3)		
Restraint	0–21	4, 6, 10, 14, 18, 21, 23, 28, 30, 32, 33, 35, 37, 38, 40, 42, 43, 44, 46, 48, 50
Disinhibition	0–16	1, 2, 7, 9, 11, 13, 15, 16, 20, 25, 27, 31, 36, 45, 49, 51,
Hunger	0–14	3, 5, 8, 12, 17, 19, 22, 24, 26, 29, 34, 39, 41, 47
Eating Inventory Subscales of Bond <i>et al.</i> (25)		
Restraint		
Strategic Dieting Behavior	0–4	6, 23, 28, 48
Attitude to Self-Regulation	0–5	10, 21, 30, 32, 37
Avoidance of Fattening Foods	0–4	33, 42, 43, 44
Disinhibition		
Habitual Susceptibility	0–5	11, 36, 45, 49, 51
Emotional Susceptibility	0–3	9, 20, 27
Situational Susceptibility	0–5	2, 7, 13, 15, 16
Hunger		
Internal Locus for Hunger	0–6	3, 5, 12, 24, 34, 39, 8,
External Locus for Hunger	0–6	19, 22, 26, 41, 47
Restraint Subscales of Westenhoefer (26)		
Flexible Restraint	0–7	4, 6, 18, 28, 35, 42, 48
Rigid Restraint	0–7	14, 32, 37, 38, 40, 43, 44

Eating Inventory

Construct	Subscale	Question	
D	none	1. When I smell a sizzling steak or see a juicy piece of meat, I find it very difficult to keep from eating, even if I have just finished a meal.	T F
D	D-S	2. I usually eat too much at social occasions, like parties and picnics.	T F
H	H-I	3. I am usually so hungry that I eat more than three times a day.	T F
R	R-F	4. When I have eaten my quota of calories, I am usually good about not eating any	T F

Eating Inventory

Construct	Subscale	Question	
H	H-I	5. Dieting is so hard for me because I just get too hungry.	T F
R	R-D, R-F	6. I deliberately take small helpings as a means of controlling my weight.	T F
D	D-S	7. Sometimes things just taste so good that I keep on eating even when I am no longer hungry.	TF
H	H-E	8. Since I am often hungry, I sometimes wish that while I am eating, an expert would tell me that I have had enough or that I can have something more to eat.	TF
D	D-E	9. When I feel anxious, I find myself eating.	TF
R	R-S	10. Life is too short to worry about dieting.	TF D D-H
		11. Since my weight goes up and down, I have gone on reducing diets more than once.	T
H	H-I	12. I often feel so hungry that I just have to eat something.	T F
D	D-S	13. When I am with someone who is overeating, I usually overeat too.	T F
R	R-R	14. I have a pretty good idea of the number of calories of common food.	T F
D	D-S	15. Sometimes when I start eating, I just can't seem to stop.	T F
D	D-S	16. It is not difficult for me to leave something on my plate.	T F
H	none	17. At certain times of the day, I get hungry because I have gotten used to eating then.	T F
R	R-F	18. While on a diet, if I eat food that is not allowed, I consciously eat less for a period of time to make up for it.	T F
H	H-E	19. Being with someone who is eating often makes me hungry enough to eat also.	T F
D	D-E	20. When I feel blue, I often overeat.	T F
R	R-S	21. I enjoy eating too much to spoil it by counting calories or watching my weight.	T F
H	H-E	22. When I see a real delicacy, I often get so hungry that I have to eat right away.	T F
R	R-D	23. I often stop eating when I am not really full as a conscious means of limiting the amount that I eat.	T F
H	H-I	24. I get so hungry that my stomach often seems like a bottomless pit.	T F
D	none	25. My weight has hardly changed at all in the last ten years.	T F
H	H-E	26. I am always hungry so it is hard for me to stop eating before I finish the food on my plate.	T F
D	D-E	27. When I feel lonely, I console myself by eating.	T F
R	R-D, R-F	28. I consciously hold back at meals in order not to gain weight.	T F
H	none	29. I sometimes get very hungry late in the evening or at night.	T FR
	R-S	30. I eat anything I want, any time I want.	T F
D	none	31. Without even thinking about it, I take a long time to eat.	T F
R	R-S, R-R	32. I count calories as a conscious means of controlling my weight.	T F

Eating Inventory			
Construct	Subscale	Question	
R	R-A	33. I do not eat some foods because they make me fat.	T F
H	H-I	34. I am always hungry enough to eat at any time.	T F
R	R-F	35. I pay a great deal of attention to changes in my figure.	T F
D	D-H	36. While on a diet, if I eat a food that is not allowed, I often then splurge and eat other high calorie foods.	T F
R	R-S, R-R	37. How often are you dieting in a conscious effort to control your weight? (1) rarely (2) sometimes (3) usually (4) always	
R	R-R	38. Would a weight fluctuation of 5 pounds affect the way you live your life? (1) not at all (2) slightly (3) moderately (4) very much	
H	H-I	39. How often do you feel hungry? (1) only at mealtimes (2) sometimes between meals (3) often between meals (4) almost always	
R	R-R	40. Do your feelings of guilt about overeating help you to control your food intake? (1) never (2) rarely (3) often (4) always	
H	H-E	41. How difficult would it be for you to stop eating halfway through dinner and not eat for the next four hours? (1) easy (2) slightly difficult (3) moderately difficult (4) very difficult	
R	R-A, R-F	42. How conscious are you of what you are eating? (1) not at all (2) slightly (3) moderately (4) extremely	
R	R-A, R-R	43. How frequently do you avoid 'stocking up' on tempting foods? (1) almost never (2) seldom (3) usually (4) almost always	
R	R-A, R-R	44. How likely are you to shop for low calorie foods? (1) unlikely (2) slightly unlikely (3) moderately likely (4) very likely	
D	D-H	45. Do you eat sensibly in front of others and splurge alone? (1) never (2) rarely (3) often (4) always	
R	none	46. How likely are you to consciously eat slowly in order to cut down on how much you eat? (1) unlikely (2) slightly likely (3) moderately likely (4) very likely	
H	H-E	47. How frequently do you skip dessert because you are no longer hungry? (1) almost never (2) seldom (3) at least once a week (4) almost every day	
R	R-D, R-F	48. How likely are you to consciously eat less than you want? (1) unlikely (2) slightly likely (3) moderately likely (4) very likely	
D	D-H	49. Do you go on eating binges though you are not hungry? (1) never (2) rarely (3) sometimes (4) at least once a week	
R	none	50. On a scale of 0 to 5, where 0 means no restraint in eating (eating whatever you want, whenever you want it) and 5 means total restraint (constantly limiting food intake and never 'giving in'), what number would you give yourself? (Check one.) (0) eat whatever you want, whenever you want it (1) usually eat whatever you want, whenever you want it (2) often eat whatever you want, whenever you want it (3) often limit food intake, but often 'give in' (4) usually limit food intake, rarely 'give in' (5) constantly limiting food intake, never 'give in'	

Eating Inventory

Construct	Subscale	Question
D	D-H	51. To what extent does this statement describe your eating behavior? 'I start dieting in the morning, but because of any number of things that happen during the day, by evening I have given up and eat what I want, promising myself to start dieting again tomorrow.'
(1) not like me (2) little like me (3) pretty good description of me (4) describes me perfectly		

Eating Inventory Constructs: R = restraint, D = disinhibition, H = hunger

Restraint Subscales: R-D = strategic dieting behavior, R-S = attitude to self-regulation, R-A = avoidance of fattening foods, R-F = flexible restraint, R-R = rigid restraint

Disinhibition Subscales: D-H = habitual susceptibility, D-E = emotional susceptibility, D-S = situational susceptibility

Hunger Subscales: H-I = internal locus for hunger, H-E = external locus for hunger

Answers in bold type accrue one point. Answers in regular type accrue zero points.

Fig. (1). Path diagram of the univariate MZA/MZT GCE twin model. MZA, monozygotic twins reared apart; MZT, monozygotic twins reared together; G, genetic factors; C, common environmental factors; E, unique environmental factors; g, c, e are path coefficients; P_1 , phenotype of twin 1; P_2 , phenotype of twin 2. Circles represent latent (unmeasured) variables. Squares represent observed (measured) variables. Single-headed arrows represent hypothesized casual relationships between variables. Double-headed arrows represent correlation or covariance between variables [20].

Eating Inventory Constructs and Subscales

Fig. (2).

Variance components from univariate GCE twin model for Eating Inventory constructs and subscales. G, genetic; C, common environmental; E, unique environmental; RES, restraint; Dieting, strategic dieting behavior; Self, attitude to self-regulation; Fat, avoidance of fattening foods; DIS, disinhibition; Habit, habitual susceptibility; Emotion, emotional susceptibility; Situation, situational susceptibility; HUN, hunger; Internal, internal locus; External, external locus.

All variables have non-statistically significant C components and statistically significant E components.

^a Statistically significant G component.

Fig. (3). Common pathway model path diagram of Eating Inventory constructs. G, genetic; C, common environmental; E, unique environmental. Rectangles represent observed variables, and the proportion of variance due to G, C and E (with 95% CI in parentheses) is printed in each rectangle. Circles represent latent or unmeasured variables. Single-headed arrows represent hypothesized casual relationships between variables. Double-headed arrows represent variance. Path coefficients are standardized parameter estimates and 95%

confidence intervals are reported in parentheses. Darkened lines indicate statistically significant paths. Subscripts indicate variable or factor under influence.

Table 1

Characteristics of Study Population [20]

	Mean \pm SD (n ^a)		<i>p</i> ^b
	MZA	MZT	
Age (years)	50.7 \pm 10.4 (47)	28.7 \pm 7.7 (85)	<0.0001
Weight (kg)	77.0 \pm 19.8 (47)	66.6 \pm 11.3 (85)	0.0066 ^c
Height (cm)	166.6 \pm 9.8 (47)	169.7 \pm 7.6 (85)	0.0798
BMI (kg/m ²)	27.5 \pm 5.4 (47)	23.1 \pm 3.4 (85)	<0.0001 ^c
Eating Inventory Constructs (3) (<i>possible scoring range in italics</i>)			
Restraint (0–21)	6.6 \pm 4.5 (45)	9.0 \pm 4.9 (84)	0.0319
Disinhibition (0–16)	5.8 \pm 3.6 (45)	5.6 \pm 3.3 (84)	0.7299
Hunger (0–14)	4.7 \pm 3.3 (45)	5.6 \pm 3.1 (84)	0.1517
Eating Inventory Subscales of Bond <i>et al.</i> (25)			
Restraint			
Strategic Dieting Behavior (0–4)	0.8 \pm 1.1 (45)	1.3 \pm 1.4 (84)	0.0539
Attitude to Self-Regulation (0–5)	1.7 \pm 1.3 (47)	2.0 \pm 1.4 (85)	0.3120
Avoidance of Fattening Foods (0–4)	2.1 \pm 1.4 (44)	2.7 \pm 1.3 (82)	0.0581
Disinhibition			
Habitual Susceptibility (0–5)	1.0 \pm 1.2 (45)	0.8 \pm 1.4 (83)	0.2308
Emotional Susceptibility (0–3)	1.1 \pm 1.1 (47)	1.0 \pm 1.1 (83)	0.7983
Situational Susceptibility (0–5)	2.2 \pm 1.6 (47)	2.2 \pm 1.3 (85)	0.8585
Hunger			
Internal Locus for Hunger (0–6)	1.9 \pm 1.8 (46)	2.5 \pm 1.9 (85)	0.0954
External Locus for Hunger (0–6)	1.7 \pm 1.5 (45)	1.7 \pm 1.5 (84)	0.8849
Restraint Subscales of Westenhoefer (26)			
Flexible Restraint (0–7)	2.1 \pm 1.8 (45)	3.1 \pm 1.8 (84)	0.0132
Rigid Restraint (0–7)	1.9 \pm 1.5 (45)	2.8 \pm 1.8 (84)	0.0300

MZA, monozygotic twins reared apart; MZT, monozygotic twins reared together

^a n, number of individuals^b *P* for statistical difference between MZA and MZT twins corrected for sampling among twins^c Differences between MZA and MZT means were not statistically significant when adjusting for age, age², and age³ (*P*>0.05).

Table 2

Intrapair MZA and MZT Correlations

	MZA		MZT	
	n ^a	Intrapair Correlation (95% CI)	n ^a	Intrapair Correlation (95% CI)
Weight (kg)	22	0.66 (0.35, 0.84)	38	0.87 (0.77, 0.93)
Height (cm)	22	0.97 (0.93, 0.99)	38	0.93 (0.87, 0.96)
BMI (kg/m ²)	22	0.55 (0.18, 0.78)	38	0.80 (0.66, 0.89)
Eating Inventory Constructs (3)				
Restraint	20	0.58 (0.20, 0.81)	37	0.64 (0.41, 0.80)
Disinhibition	20	0.41 (-0.02, 0.71)	38	0.54 (0.27, 0.73)
Hunger	20	0.42 (-0.01, 0.72)	38	0.42 (0.12, 0.65)
Eating Inventory Subscales of Bond <i>et al.</i> (25)				
Restraint				
Strategic Dieting Behavior	20	0.35 (-0.08, 0.68)	38	0.30 (-0.02, 0.56)
Attitude to Self-Regulation	22	0.39 (-0.02, 0.69)	38	0.43 (0.13, 0.65)
Avoidance of Fattening Foods	19	0.62 (0.25, 0.83)	36	0.53 (0.25, 0.73)
Disinhibition				
Habitual Susceptibility	20	0.32 (-0.12, 0.66)	36	0.53 (0.25, 0.73)
Emotional Susceptibility	22	0.60 (0.25, 0.81)	37	0.60 (0.35, 0.77)
Situational Susceptibility	22	0.47 (0.07, 0.74)	38	0.38 (0.08, 0.62)
Hunger				
Internal Locus for Hunger	21	0.58 (0.21, 0.80)	38	0.41 (0.11, 0.64)
External Locus for Hunger	20	0.37 (-0.07, 0.69)	38	0.25 (-0.07, 0.52)
Restraint Subscales of Westenhoefer (26)				
Flexible Restraint	20	0.39 (-0.04, 0.71)	37	0.49 (0.21, 0.70)
Rigid Restraint	20	0.58 (0.21, 0.81)	37	0.57 (0.31, 0.75)

MZA, monozygotic twins reared apart; MZT, monozygotic twins reared together.

^an, number of twin pairs.

Table 3

Variance Components from Univariate GCE Model for Eating Inventory Constructs and Subscales

	Proportion of Variance (95% CI)		
	Genetic	Common Environmental	Unique Environmental
Eating Inventory Constructs (3)			
Restraint	0.52 (0.10, 0.69)	0.03 (0.00, 0.48)	0.45 (0.28, 0.67)
Disinhibition	0.37 (0.00, 0.62)	0.14 (0.00, 0.61)	0.50 (0.31, 0.76)
Hunger	0.37 (0.00, 0.59)	0.04 (0.00, 0.54)	0.58 (0.37, 0.83)
Eating Inventory Subscales of Bond et al. (26)			
Restraint			
Strategic Dieting Behavior	0.31 (0.00, 0.57)	0.00 (0.00, 0.45)	0.69 (0.42, 1.00)
Attitude to Self-Regulation	0.36 (0.00, 0.58)	0.00 (0.00, 0.41)	0.64 (0.41, 0.91)
Avoidance of Fattening Foods	0.40 (0.00, 0.64)	0.00 (0.00, 0.48)	0.60 (0.34, 0.92)
Disinhibition			
Habitual Susceptibility	0.30 (0.00, 0.64)	0.11 (0.00, 0.69)	0.59 (0.27, 0.98)
Emotional Susceptibility	0.55 (0.11, 0.75)	0.00 (0.00, 0.49)	0.45 (0.23, 0.71)
Situational Susceptibility	0.38 (0.04, 0.59)	0.00 (0.00, 0.35)	0.62 (0.40, 0.88)
Hunger			
Internal Locus for Hunger	0.50 (0.15, 0.69)	0.00 (0.00, 0.36)	0.50 (0.31, 0.75)
External Locus for Hunger	0.29 (0.00, 0.52)	0.00 (0.00, 0.42)	0.71 (0.46, 0.98)
Restraint Subscales of Westenhoefer (27)			
Flexible Restraint	0.11 (0.00, 0.50)	0.27 (0.00, 0.62)	0.62 (0.37, 0.94)
Rigid Restraint	0.48 (0.00, 0.67)	0.00 (0.00, 0.54)	0.52 (0.30, 0.77)

Table 4
 Variance-covariance and Correlation Matrices of Eating Inventory Constructs for MZAs and MZTs

Monozygotic Twins Reared Apart (MZA)						
Construct	RES1	DIS1	HUN1	RES2	DIS2	HUN2
RES1	20.81	-0.04	-0.21	0.58	-0.11	-0.34
DIS1	-0.77	14.22	0.35	-0.09	0.40	-0.16
HUN1	-2.95	4.12	9.80	0.03	0.21	0.45
RES2	12.06	-1.50	0.39	20.36	0.14	-0.18
DIS2	-1.59	4.68	1.94	2.11	11.58	0.33
HUN2	-5.25	-2.05	4.55	-2.77	3.77	11.37
Monozygotic Twins Reared Together (MZT)						
Construct	RES1	DIS1	HUN1	RES2	DIS2	HUN2
RES1	25.05	0.39	0.12	0.64	0.16	0.10
DIS1	6.73	11.64	0.39	0.46	0.54	0.40
HUN1	1.68	3.81	8.06	0.28	0.31	0.42
RES2	15.35	7.70	3.71	22.56	0.18	-0.01
DIS2	2.77	6.29	2.98	2.72	10.50	0.57
HUN2	1.84	4.94	4.13	-0.09	6.30	11.73

Variances are on the leading diagonal, covariances are below the diagonal, and correlations are above the diagonal. RES, restraint; DIS, disinhibition; HUN, hunger. Numbers at the end of the variable name indicate twin 1 or twin 2
